## Syllabus

In addition to individuals, populations and communities are important ecological entities. Plant species associating on certain sites form plant communities, which in turn, provide the basis for animal communities. Shifts in site conditions or successions result in a gradual turnover of species occurrences, both in plants and animals, that are linked in multiple and complex ways. Ecosystem management is based, in part, on population management by enhancement or suppression, respectively. Management goals include harvesting, conservation, and control of populations.

Basic principles of population dynamics (biotic as well as abiotic factors) are significant for the understanding of various types of population dynamics. Some contexts are particularly highlighted because different factors have different impact according to species or management context:

- · Insect populations: examples for communities and their dynamics
- Wildlife Ecology: introduction to wildlife population ecology as a basis of wildlife management
- Neobiota: influences of alien species on their 'new' environment
- Relationships between sites and vegetation; indicator values of species
- Plant formations and communities: Concepts, definitions, examples
- Ecological gradients

## Learning goals and qualifications

In this module students learn and study biological basics of populations and communities such as structure, dynamics, and determining factors. Major objective is to understand relationships between pedology, climatology, species compositions; the formation of plant and animal communities and populations, their ecological function, the relations among animals and between plants and animals. Furthermore, cases are presented and analysed to understand complexity of biotic and abiotic influences.

Since every single problem of managing populations is unique; case studies are used to develop general principles and concepts that can be transferred to analyse any case for identifying biological factors crucial for management approaches. Students will be enabled to develop and implement adapted concepts and to consider and synthesize information from other sources (literature, modules).

Lectures, tutorials	
Prerequisites	
none,	
recommended: propaede	utic self-study
Requirements for registra	tion
None	
Distribution of workload	
Contact hours	60 h (lectures, exam)
Independent learning	65 h (preparation, reading)
Proposed assessment	
written exam (75%)	
homework thesis (25%)	
Link to learning resources	6
CampusOnline
